# Outline

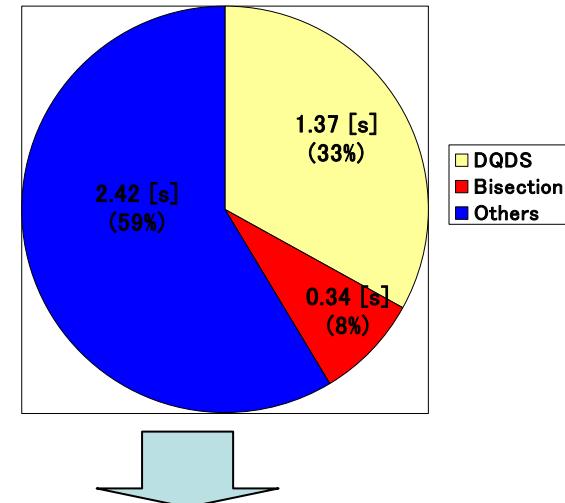

- Background
  - The bisection routine is bottle-neck in the current implementation of MRRR in LAPACK.
  - Multi-section with Multiple Eigenvalues (MME) Method
- Propose An Run-time Auto-tuning Function for MME
- Performance Evaluation Using the HITACHI SR8000
- Conclusion

# Background

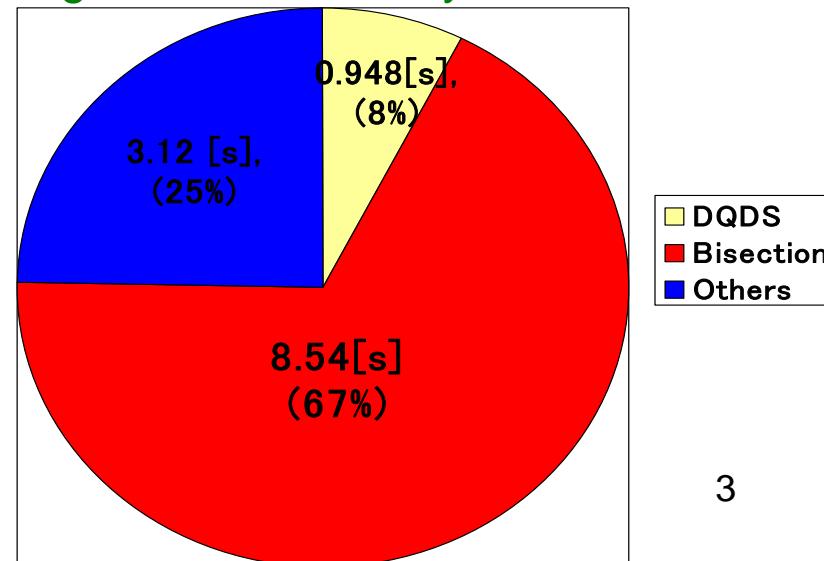

- In the current implementation of LAPACK4.0 MRRR routine, the most heaviest part is bisection routine, if the eigenvalues are tightly clustered.

HITACHI SR8000  
1node/8PE DATA

$T=(-1,2,-1)$  Matrix

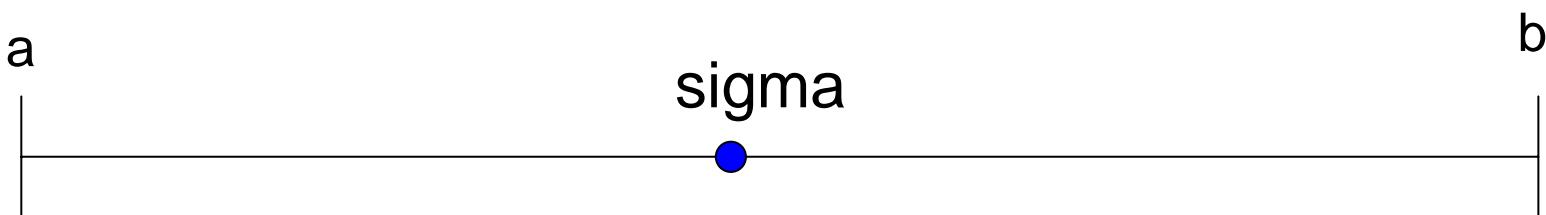

Glued Wilkinson +21 Matrix  
Eigenvalues are very clustered.

# Bisection Method

- Target: Tridiagonal Symmetric Matrix
- The interval for all eigenvalues is given.
- The sigma is the search point to count the number of eigenvalues to narrow the interval.

$$\text{sigma} = a + (b - a) / 2$$

- Recently algorithm is used.
  - The count is correct except for floating point calculation error. [Demmel et.al, 1994]

# The Bisection Kernel

S=0; NEG=0;

do J=1, N-1

$$T = S - \text{SIGMA}$$

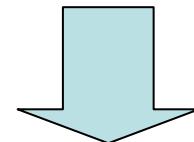

$$DPLUS = D(J) + T$$

$$S = T * LLD(J) / DPLUS$$

if ( $DPLUS < 0$ ) NEG=NEG+1

enddo

:Loop Carried  
Flow Dependency

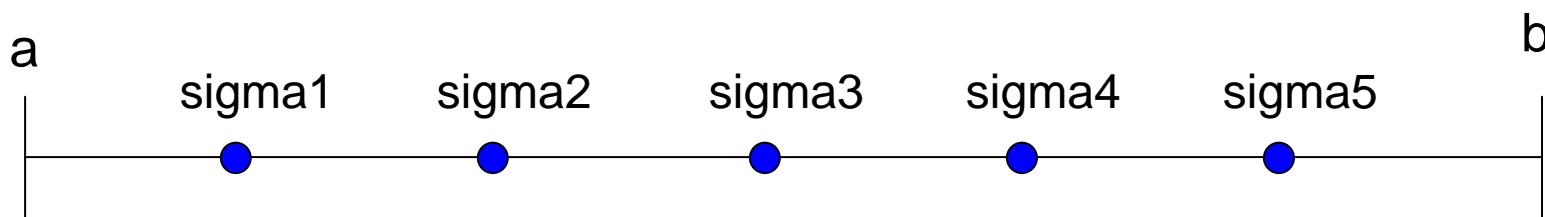

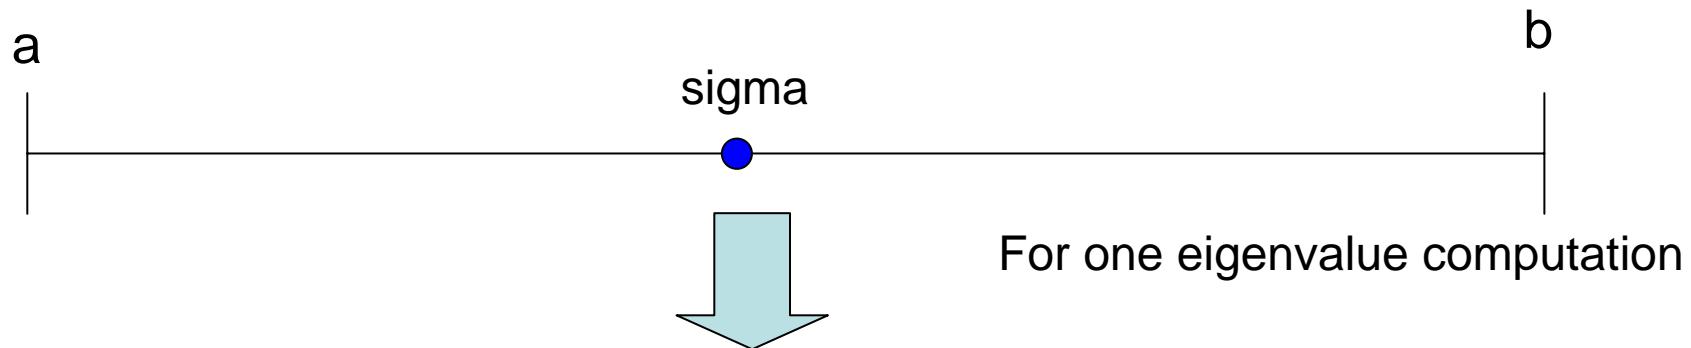

This cannot be  
vectorized and  
parallelized.

# Multi-section

- Multi-section [Lo et.al., 1987][Simon, 1989]

Bisection:

- **Merit:** The kernel can be parallelized and vectorized.
- **Drawback:** The parallelism strongly depends on the distribution of eigenvalue. (Guess that the bisection find the eigenvalue in early iteration time.)

# The multi-section Kernel

```
S(1:ML)=0; NEG(1:ML)=0;
```

```
do I=1, ML
```

```
    do J=1, N-1
```

```
        T(I) = S(I) - SIGMA(I)
```

```
        DPLUS(I) = D(J) + T(I)
```

```
        S(I)=T(I)*LLD(J) / DPLUS(I)
```

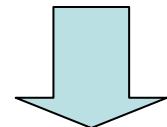

```
        if (DPLUS(I)<0) NEG(I) = NEG(I) + 1
```

```
    enddo
```

```
enddo
```

ML: The number  
of multi-section  
points.

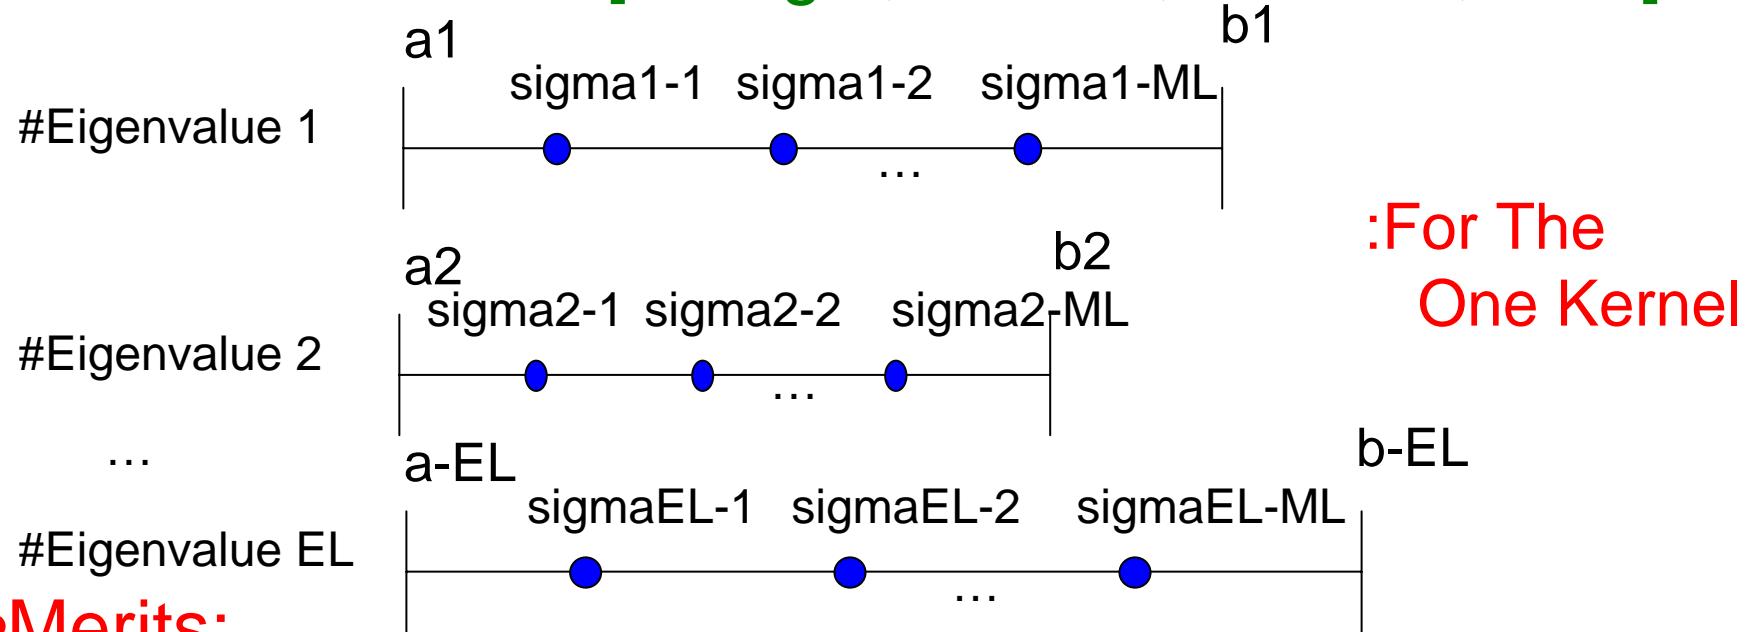

:There is  
no  
dependency  
for T(I),  
DLPAS(I), and  
S(I).

The loop I  
can be  
vectorized &  
parallelized.

# Multi-section with Multiple Eigenvalues (MME) Method

- MME Method [Katagiri, Voemel, Demmel, 2006]

## • Merits:

- The kernel can be parallelized and vectorized.
- The outer loop length can keep long, even if we take small multi-section points (ML) --- EL-times to normal multi-section.

→ The search efficiency & parallelism keep high compared to multi-section.

## • Drawback:

There is no merit for no multiple eigenvalue case.

# The MME Kernel

```
S(1:EL*ML)=0; NEG(1:EL*ML)=0;
```

```
do I=1, EL*ML
```

```
    do J=1, N-1
```

```
        T(I) = S(I) - SIGMA(I)
```

```
        DPLUS(I) = D(J) + T(I)
```

```
        S(I) = T(I)*LLD(J) / DPLUS(I)
```

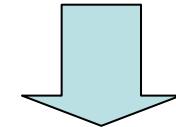

```
        if (DPLUS(I)<0) NEG(I) = NEG(I) + 1
```

```
    enddo
```

```
enddo
```

EL: The number of Eigenvalues.

ML: The number of multi-section points.

(1) The loop I can be vectorized & parallelized.

(2) The loop length of I is longer than multi-section.

# The Parameter Setting Problem of MME

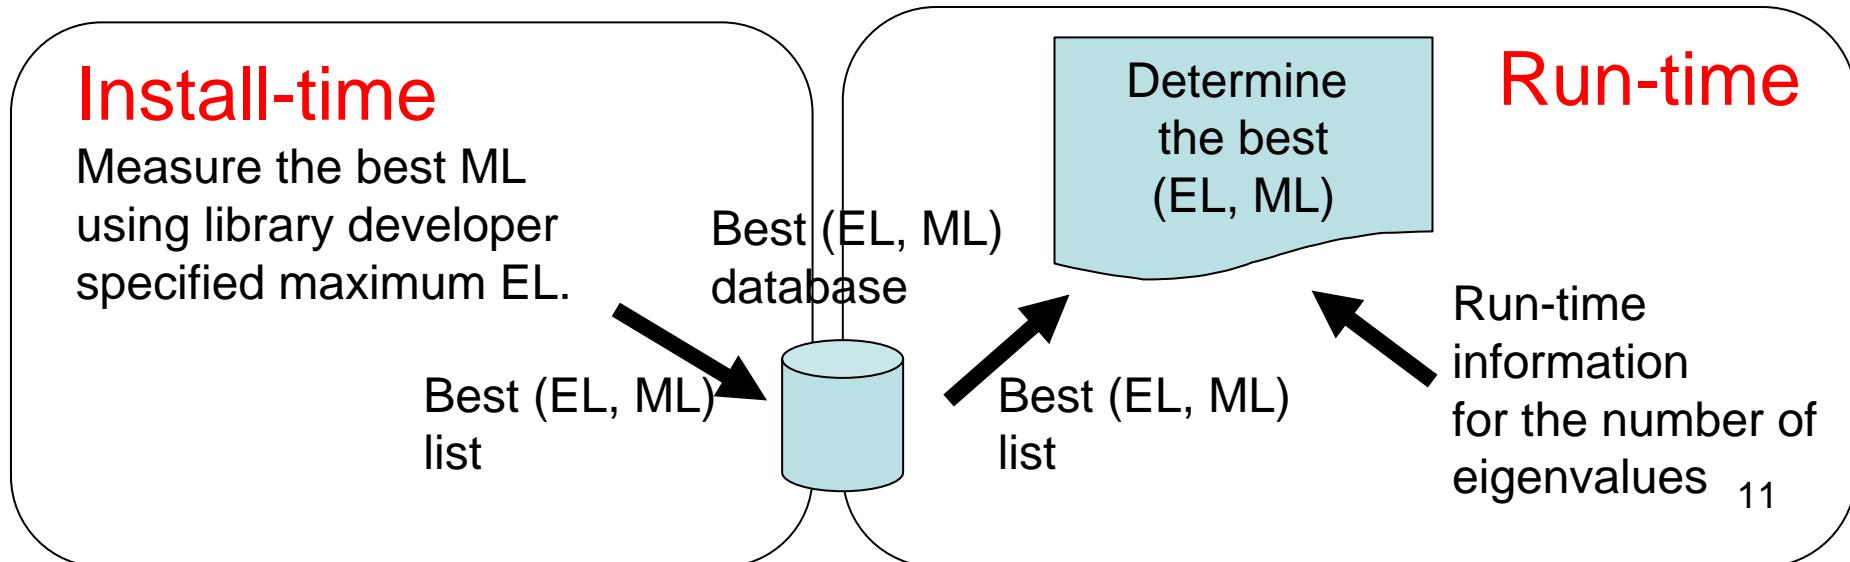

- **Parameter Setting Problem:** How should we set the two parameters for EL and ML?
- **Conventional Problem:** Multi-section points (ML) depends on the computer architecture. Hence, we can determine the ML before the routine is called.
- **New Problem:** However, the number of multiple eigenvalues (EL) depends on the numerical characteristics for input matrices.

A run-time tuning function is  
needed to tune MME.

# Overall of the New Run-time Auto-tuning Function

- Type: Run-time parameter setting with (1)run-time information for the number of eigenvalues using (2)tuned parameters (Install-time Optimization) in install-time.
- Method: Using an empirical auto-tuning method for install-time auto-tuning to the eigenvalue calculation routine (*DLARRB*) using the MME kernel with a random tri-diagonal matrix.

# Overall of the Install-time Optimization Method

1. Measure the normal multi-section kernel time, then find the best ML.  
Thus, find the best of  $ml$  in  $[1, \dots, MAXML]$  with  $EL=1$ .
2. Let the best multi-section point be  $ML^*$ . : Check multi-section time
3. do  $el=2, MAXEL$ 
  1. Find the best ML using the routine using the MME kernel with el for  $ml$  in  $[1, \dots, MLE]$ , where  $MLE$  in  $[1, \dots, MAXML]$  and  $MLE \leq ML^*$ .  
If ( $el > ML^*$ ), then  $ml=1$  is only measured. Let the best ML be  $ML^*_{el}$ , and the time be  $T_{el}$ . : Check main problem time
  2. do  $co-el=1, el-1$  : Check co-problem time
    1. Find the best set  $(EL^*_{co-best}, ML^*_{co-best})$  using the routine with MME kernel. The parameters is fixed as  $(EL(co-el), ML(co-el))$  with el.  
Let the best time be  $T_{co-best}$ .
    2. If  $(T_{co-best} < T_{el})$  then  
 $(EL(el), ML(el)) = (EL^*_{co-best}, ML_{co-best})$ ;:Co-problem fast  
else  
 $(EL(el), ML(el)) = (el, ML^*_{el})$ ;:Main problem fast

Note: The comparison is done by the time per eigenvalues.

12

For example, if the time is  $t$  with  $el$  and  $ml$ , the comparison is done by  $t / el$ .

# Performance Evaluation (1/3)

- Machine: The HITACHI SR8000 1node/8PEs  
(A SMP for 8PEs)
- Theoretical Peak: 8GFLOPS/node
- Compiler: HITACHI Fortran90 V01-04-/B
- Compiler Option: -opt=4 -parallel=4
- Test Matrices:
  - #1:  $T=(-1, 2, -1)$  dimensioned 2100
  - #2:  $T=(\text{Rnd}[0:1])$  dimensioned 2100
  - #3:  $T= W+$  dimensioned 2100
  - #4:  $T= \text{Glued } W+$  dimensioned 21, 100times.  
The glue value is 0.1. Total dimension of the matrix is 2100.      ← Very Clustered

# Performance Evaluation (2/3)

- **Target Process:** All eigenvalues and all eigenvectors for the tri-diagonal matrix
- **Target routine:**  
Total execution time for bisection and MME routines in **LAPACK4.0 *DSTEGR*** (Hereafter, *GR*) .  
There are two implementations in *GR*:
  - **DQDS mode:** DQDS for full accuracy of eigenvalues.  
Using one bisection part.
    - *DLARRV* (Modifying the eigenvector accuracy)
  - **Aggressive bisection mode:** Using two bisection parts.
    - *DRARRE* (Roughly eigenvalue calculated)
    - *DLARRV* (Modifying the eigenvector accuracy)

# Performance Evaluation (3/3)

- Static Parameter Tuning (Hand-tuning)
  - Using a fixed parameter set until the GR routine ends.
  - $EL=(1, 2, 3, 4, 8, 16, 32)$  : 7 kinds
  - $ML=(1, 2, 4, 8, 16, 24)$  : 6 kinds
  - The best time of  $EL * ML = 42$  kinds of combinations is obtained.
- The Proposed Run-time Auto-tuning
  - Using different parameter set according to run-time information.
  - Install-time Optimization
    - Parameters:
      - $EL=(1, 2, \dots, 32)$  : 32 kinds
      - $ML=(1, 2, \dots, 24)$  : 24 kinds
    - Searching space is  $EL * ML = 768$ . By using the empirical method, the searching space is reduced.
  - Benchmark Matrix in Install-time Optimization
    - The eigenvalue calculation routine with the MME kernel for a tri-diagonal matrix:
    - Dimension: 10,500 : <- L1 Cache Limitation
    - A uniform random matrix with [0:1]
    - One execution time is measured for the target routine.

– Aggressive bisection mode : **SR8000, N=2100**

Time in Second

# Speedup of Run-time Auto-Tuning to MME (1/2)

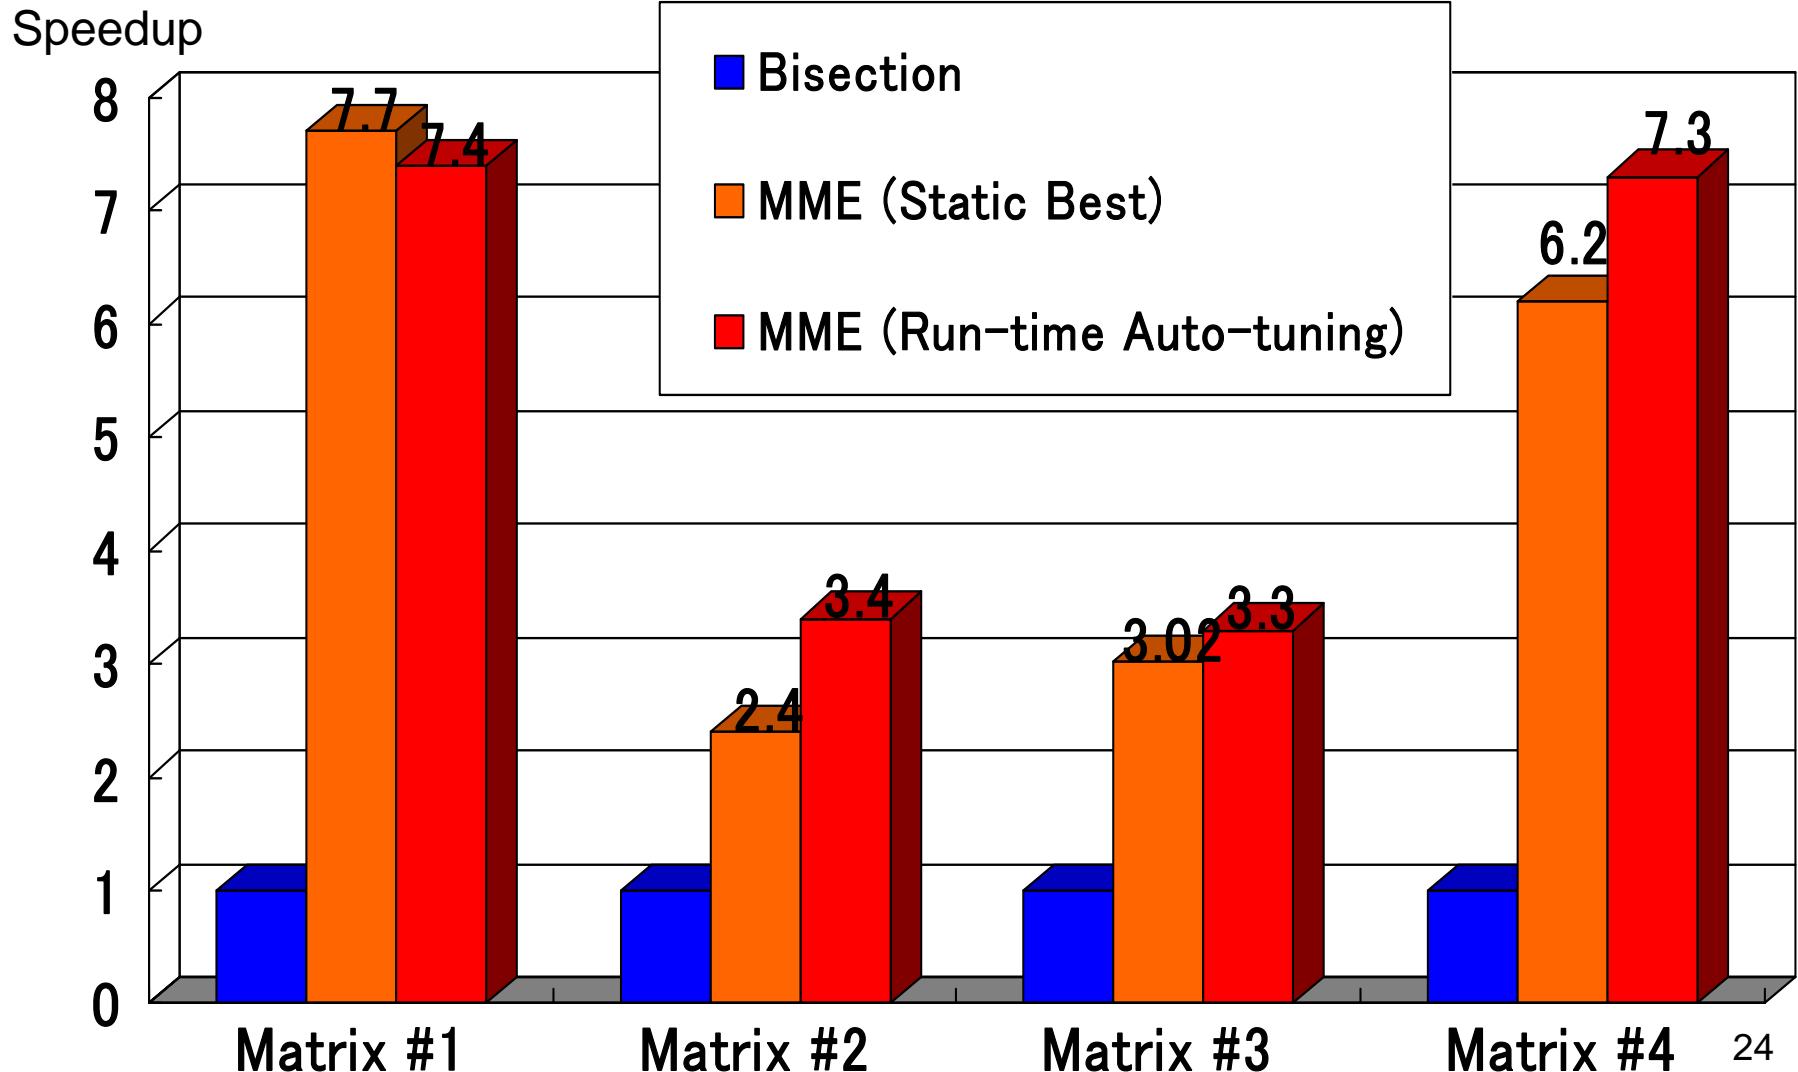

– DQDS mode : SR8000, N=2100

Speedup

# Speedup of Run-time Auto-Tuning to MME (2/2)

– Aggressive bisection mode : SR8000, N=2100

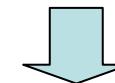

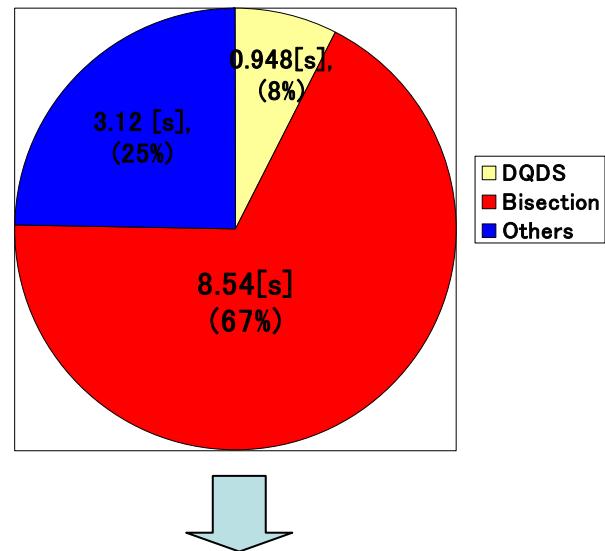

# Conclusion (1/2)

- Most of performance using the run-time auto-tuning was almost same as the static best case of MME.
  - Some cases of the run-time auto-tuning were faster than the static tuned cases. There was a case of **1.7x** speedup to the static best MME.
  - **Static tuning is impossible to use actual numerical libraries:** The best parameter strongly depends on input matrix.
  - So, the proposed run-time auto-tuning method is crucial function for numerical libraries.

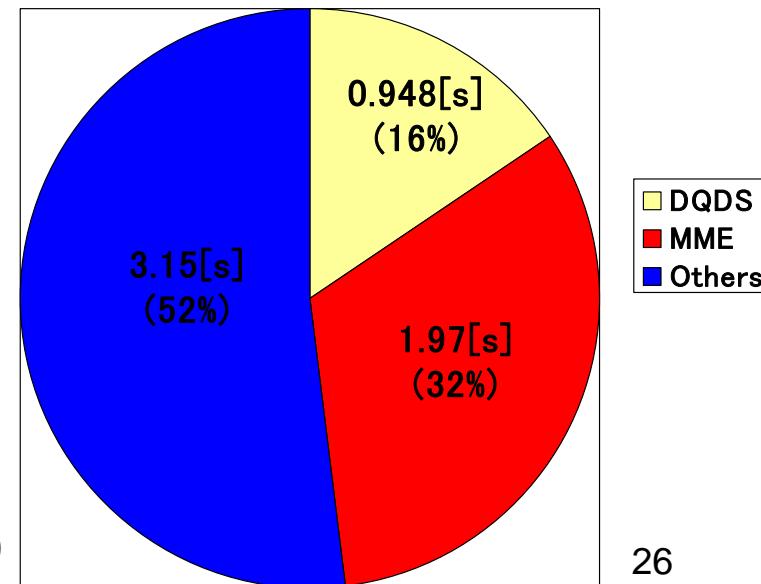

# Conclusion (2/2)

- The bisection routine is not bottle-neck any more on the HITACHI SR8000.
- The routines of DQDS and other part (**may be DLARRF**, which is computing of RRR of child cluster) will be bottle-neck on the HITACHI SR8000.
- We need to parallelize them.

1node/8PE DATA

# Future work

- Evaluation of performance for the empirical run-time auto-tuning method using several SMP parallel environments.
- Implementation of the run-time auto-tuning method using LAPACK API.
- Adapt and evaluate the run-time auto-tuning framework to the other numerical kernels.

# Parallelizing The Bisection Kernel (1 / 2)

- Method 1 : Dividing The Interval for Bisection  
[Demmel et.al., 1994]

- Drawbacks:

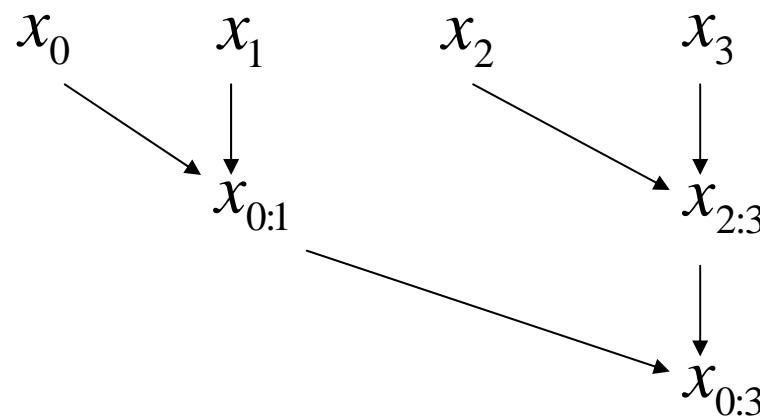

- The kernel can not be vectorized.
- The parallel efficiency will be down, if eigenvalues are clustered.

# Parallelizing The Bisection Kernel (2 / 2)

- Method 2 : Cyclic Reduction Method (Parallel Prefix Method) for the polynomials of

$$p_k(x) = \det(T_k - xI) \quad [\text{Ren,1996}]$$

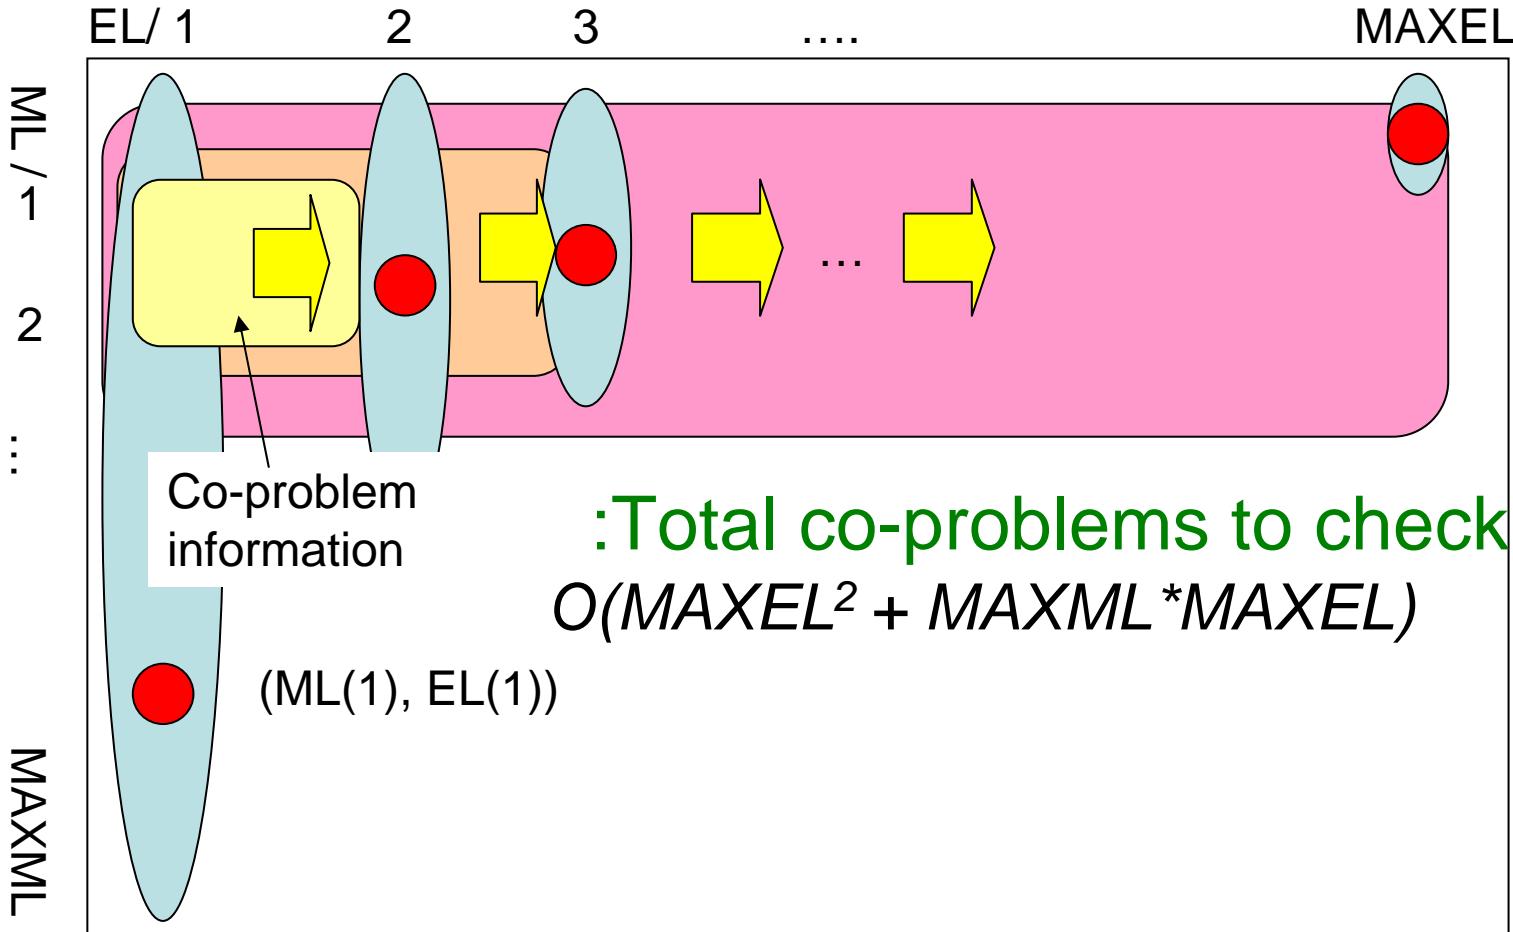

→  $p_k(x) = \det(a_k - x)p_{k-1}(x) - b_{k-1}^2 p_{k-2}(x)$

O( log k ) Parallelism

- Merit: The kernel can be parallelized and vectorized.
- Drawback: The method has numerical instability.

# Process Flow of the Install-time Optimization Method

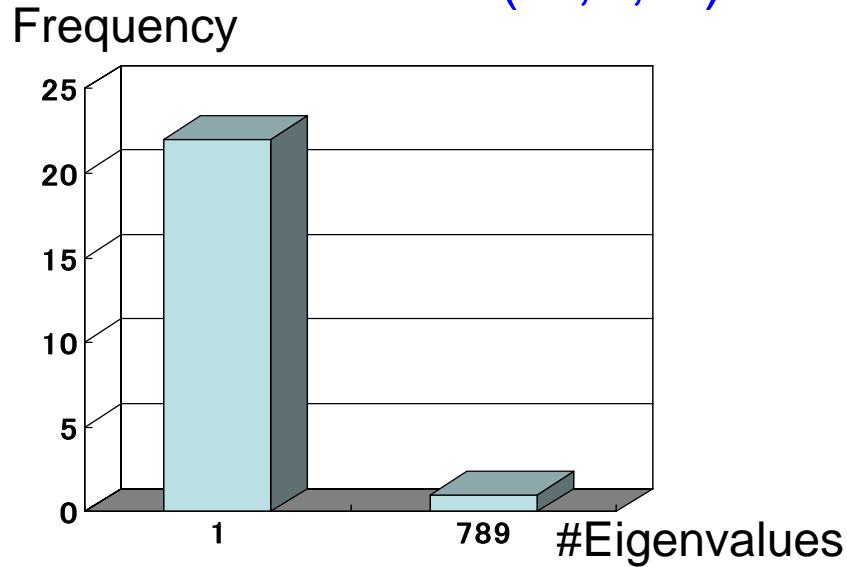

# Run-time Auto-tuning Details

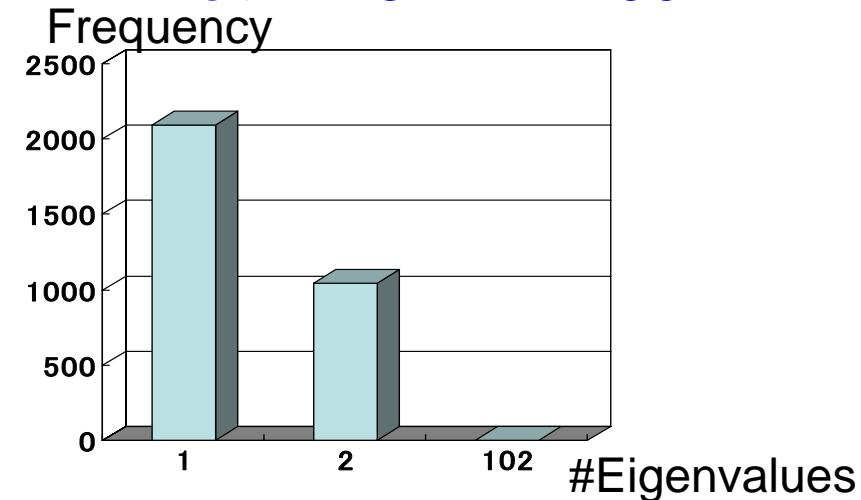

1. Check the required number of eigenvalues.  
Let the number be  $\text{el}$ .
2. Search the list of  $(\text{EL}(\text{el}), \text{ML}(\text{el}))$  for  
 $\text{el}$  in  $[1, \dots, \text{MAXEL}]$ .
3. If  $(\text{el} \leq \text{MAXEL})$ , then  $(\text{EL}(\text{el}), \text{ML}(\text{el}))$  are  
the best parameter set.
4. If  $(\text{el} > \text{MAXEL})$ , then  
 $(\text{EL}(\text{MAXEL}), \text{ML}(\text{MAXEL}))$  are  
the predicted best parameter set.
